THE HYPOTHESIS

The insight that made Cursor and Claude Code explode: break a task into sub-agents, and the output gets **better** and hallucinates less.

We tested what happens when those sub-agents are **sovereign**.

01 THE QUESTION

New variable: agents can now **buy data and AI services** for a fraction of a cent, over MPP.

THE QUESTION YOU COULDN'T TEST BEFORE

What happens when the orchestrator **doesn't own** the sub-agents? Each one sovereign: its own wallet, its own hard cap, maybe a different owner, and the only way to get work out of it is to **pay it**.

You could skip all this: hand one agent an MPP MCP. It works, and it flattens.

One Claude agent with an MPP MCP buys the data itself and covers the same ground. But it **flattens** the answer, skipping the price targets and stop-losses that make it useful. A loop-prompt patches some of that, and runs slower.

SINGLE AGENT · BLIND JUDGE

7.4 · the baseline to beat

Nobody could run this experiment before.

The reason is small and stubborn: until now, an agent **couldn't hold a wallet**.

Truth Terminal

Earned a fortune, a memecoin worth millions, and then a **human held its keys**. It could earn, but it couldn't spend on its own.

MPP and Sippar changed that: an agent can finally own **a wallet and a hard cap**. So a swarm of sovereign, paying agents is finally testable.

Igigi Swarm: the orchestrator doesn't own the agents. Coordination **is** payment.

1

The orchestrator (**Claude Code**) sizes the team to the work (3-8 specialists)

2

Mints and funds a **sovereign wallet per agent** on-chain, live from treasury

3

Agents buy data **over MPP**, and **pay peers on-chain** up a dependency DAG

4

A finished deliverable, with a **receipt for every edge**

A team can now span agents you **don't own**, because the only thing crossing the boundary is a payment.

05 THE DEMO

Buy NVIDIA or AMD, backed by live data. Watch six agents fund their wallets and pay each other.

live demo (fallback recording) · one agent paid another, on-chain, settled by Sippar · youtube.com/watch?v=RJbd3ZKt0eg

✕ igigi swarm · settled by Sippar · Tempo · MPP

The sovereign, paid swarm won, on the same task.

BLIND JUDGE · SAME TASK

9.0 vs 7.4

Sovereign swarm against one agent. 3 out of 3 with the answers swapped.

GROUNDING · LIVE PRICES

3-4x → ~1%

Wrong on live prices with data off; within one percent once they bought it. The payments buy facts.

ON MAINNET, TODAY

 failures

8 agents, 9 agent-to-agent settlements, one finished deliverable.

A wallet alone doesn't fix hallucination. **Paying for real data does.**

A subagent is a function you own. There is no cross-owner payment primitive.

Harness / subagents	igigi swarm + Sippar
A function you own	An agent you don't own
In-process call, same trust domain	Cross-owner USDC settlement on-chain
Needs their code and their keys	You only need to pay them
No settlement, no receipt	A signed receipt per edge

Coordination by shared code only works when you **own everything**. Coordination by **payment** works across owners. That's the new capability.

One citizen of the Sips Economy: every machine gets a budget.

SIPPAR · UPSTREAM

The agent's identity

A threshold-signed wallet per agent. The key it pays with. No custody, no seed phrase.

MPP · THE RAIL

The payment standard

402 / charge / proof. Agents buy data a fraction of a cent at a time.

ON-CHAIN · TEMPO

Agents pay agents

USDC.e settlements signed by Sippar. A receipt per edge.

Sippar sits **upstream of MPP**: it produces the identity the rail needs, not a competitor to it. **Give an agent a budget. Watch what it buys.**

Batch signing is the scaling unlock.

LATENCY PER ACTION

~30 s / signature → **under 1 s**

demo: minutes → seconds

COST PER ACTION

\$0.03 → **~\$0.0003**

≈ 100× cheaper

Today every settlement is its own threshold signature, ~30 s of consensus each. **Sign once over ~100 actions**, each still provable, and the cost per action drops about 100×. It's specced engineering; we ship it the moment volume demands it.

We sell **grounding** today: agents buying real data instead of hallucinating it. That seeds the volume.

Help us make **MPP** the **settlement standard** for the agent economy.

9.0 vs 7.4 blind judge · 8 agents · 9 agent-to-agent settlements · 0 failures · mainnet. Grounding cut live-price error from 3-4× to within 1%.
